

Package ‘RcometsAnalytics’

January 24, 2023

Type Package

Title Comets Analytics for consortium based metabolomic analyses

Version 2.9.0.4

Author Ella Temprosa, Ewy Mathe

Maintainer Bill Wheeler <wheelerb@imsweb.com>

Description This R package support all cohort-specific analyses of the COMETS consortium. Data are not saved in the system but output must be downloaded and submitted for meta-analyses. This package can be used in several ways: supports the CBIIT implementation of comets-analytics, local shiny based add-in called shinycomets, or console based analysis. See example vignette. The version of the package is noted as: level 1 and 2 reflect the comets-analytics version, 3rd level reflects the number of major revision and 4th level for bug fixes.

Depends R (>= 3.5.0)

Imports readxl, rio, dplyr, plyr, plotly, tidyr, heatmaply, stringr,
data.table, caret, subselect, broom, psych, MASS, ppcor,
survival

Suggests Hmisc, knitr, testthat, rmarkdown

VignetteBuilder knitr

License GPL-3

RoxygenNote 7.2.1

NeedsCompilation no

RcometsAnalytics-package

RcometsAnalytics R package

Description

This R package supports all cohort-specific analyses of the COMETS consortium <https://www.comets-analytics.org/>. Data are not saved in the system but output must be downloaded and submitted for meta-analyses.

Details

Functions for analysis:

[runCorr](#) (correlation analysis)

[runModel](#) (correlation, glm, lm, coxph, or clogit)

[runAllModels](#) (run models in batch mode from models sheet)

Functions for graphics:

[plotVar](#) (metabolite variance distribution plot)

[plotMinvalues](#) (distribution of missing values)

[showHeatmap](#) (heat map of metabolite correlations)

[showHClust](#) (interactive heat map with hierarchical clustering)

Functions for saving results to files:

[OutputCSVResults](#) (write to .csv file)

[OutputXLSResults](#) (write to excel file)

[OutputListToExcel](#) (write list of data frames to excel file with multiple sheets)

Functions for meta-analysis:

[runMeta](#) (run a single meta-analysis)

[runAllMeta](#) (run multiple meta-analyses)

[meta_calc](#) (main calculation function for meta-analysis)

clogit.options	<i>options list for clogit</i>
----------------	--------------------------------

Description

A list of 2:

- method One of: "exact", "approximate", "efron", "breslow". The default is "exact".
- weights A variable name to specify weights. The default is NULL.

Examples

```
model.options <- list(method="efron", weights="weightVarInData")
```

correlation.options	<i>options list for model="correlation"</i>
---------------------	---

Description

A list of 1:

- method Correlation method to use. It must be one of "spearman", "pearson", "kendall". The default value is "spearman".

Examples

```
model.options <- list(method="pearson")
```

coxph.options	<i>options list for coxph</i>
---------------	-------------------------------

Description

A list of 6:

- ties One of: "efron", "breslow", "exact". The default is "efron".
- robust TRUE or FALSE for computing a robust covariance matrix). The default is FALSE.
- weights A variable name to specify weights. The default is NULL.
- singular.ok See [coxph](#). The default is TRUE.
- Surv.type See the type option in [Surv](#). The default is NULL.

Examples

```
model.options <- list(robust=TRUE, weights="weightVarInData")
```

Effects	<i>Effects table</i>
---------	----------------------

Description

The Effects data frame contains the estimates for each exposure, and will contain multiple rows for categorical exposure variables. Depending on the model run and options specified, all the below names may not appear in the data frame.

- `corr` The correlation between term and the outcome
- `estimate` The regression coefficient of term
- `estimate.lower` The lower confidence limit for term
- `estimate.upper` The upper confidence limit for term
- `exp.estimate` The exponentiated regression coefficient of term
- `exp.estimate.lower` The exponentiated lower confidence limit for term
- `exp.estimate.upper` The exponentiated upper confidence limit for term
- `exp.std.error` The standard error of `exp.estimate` from the delta method
- `exposurespec` Exposure variable
- `model` Model label from [getModelData](#)
- `model_number` Model number used in [runAllModels](#)
- `outcomespec` Outcome variable
- `pvalue` The p-value of the test
- `run` Run number that can be used to link with the [ModelSummary](#) table
- `statistic` The test statistic for term
- `std.error` The standard error of estimate
- `stratavar` Stratum variable(s)
- `strata` Stratum level(s)
- `term` Variable in the model

Details

Missing values will appear if a model did not converge, produced an error, or not run because of too many missing values in the outcome.

Errors_Warnings	<i>Errors and Warnings table</i>
-----------------	----------------------------------

Description

Columns in the Errors_Warnings table.

- type WARNING or ERROR
- object The object that produced the warning or error. This is typically a variable or a particular stratum.
- message Message describing the warning or error
- model Model label from [getModelData](#)
- model_number Model number used in [runAllModels](#)

Details

The kinds of warnings and errors stored in this matrix are ones that apply to all models or all outcomes for an exposure variable. An error message for a particular exposure-outcome pair will be stored in the message column of the [ModelSummary](#) table.

filterCOMETSinput	<i>Function that subsets input data based on "where variable"</i>
-------------------	---

Description

Function that subsets input data based on "where variable"

Usage

```
filterCOMETSinput(readData, where = NULL)
```

Arguments

readData	list from readComets
where	users can specify which subjects to perform the analysis by specifying this parameter. 'where' expects a vector with a variable name, a comparison operator (" $<$ ", " $>$ ", " $=$ ", " $<=$ ", " $>=$ "), and a value. For example, "where = c("Gender=Female")".

Value

filtered list

getModelData	<i>Prepares data for the models to be run as specified in the input. Can be run in interactive or batch mode. Each model is checked for validity (correlation between predictors, zero variance, etc.).</i>
--------------	---

Description

Prepares data for the models to be run as specified in the input. Can be run in interactive or batch mode. Each model is checked for validity (correlation between predictors, zero variance, etc.).

Usage

```
getModelData(
  readData,
  modelspec = "Batch",
  modlabel = "",
  outcomes = "All metabolites",
  exposures = "",
  adjvars = NULL,
  strvars = NULL,
  wgtvar = NULL,
  offvar = NULL,
  timevar = NULL,
  groupvar = NULL,
  where = NULL,
  exposurerefs = NULL
)
```

Arguments

readData	List from readCOMETSinput
modelspec	How model is specified (Interactive or Batch). The default is Batch
modlabel	If batch, chosen model specified by batch mode (the MODEL column in the Models sheet). If interactive, then the model label.
outcomes	If Interactive, a vector of outcome variables (see details), the default is All metabolites)
exposures	If Interactive, a vector of exposure variables (see details)
adjvars	If Interactive, a vector adjustment covariates (see details)
strvars	If Interactive, stratification covariates (see details)
wgtvar	If Interactive, a variable of weights (see details)
offvar	If Interactive, an offset variable (see details)
timevar	If Interactive, time variable(s) for survival models (see details)
groupvar	If Interactive, a group variable for conditional logistic models (see details)
where	users can specify which subjects to perform the analysis on by specifying this parameter. 'where' expects a vector of strings with a variable name, a comparison operator (e.g. "<", ">", "<=", ">=", "!=", "="), and a value. For example, where = c("age>50", "bmi > 22") uses all subjects with age > 50 AND bmi > 22. Note that when running in Batch mode, rules in the WHERE column of the Models sheet must be separated by a comma.

exposurerefs If Interactive, a vector of exposure reference levels for categorical exposure variables. If specified, then this vector must have the same length as exposures.

Details

All metabolite variables specified should be listed in the `metabolite_name` column of the Metabolites sheet of the Excel file. All non-metabolite variables should be listed in the `VARREFERENCE` column of the VarMap sheet. The `wgtvar`, `offvar`, and `timevar` are only used for specific models. See the `model` option in [options](#).

Value

a list comprising:

- 1: subset data: `gdta`
- 2: exposure variables: `ccovs`
- 3: outcome variables: `rcovs`
- 4: adjustment variables: `acovs`
- 5: stratification variable: `scovs`
- 6: model specification: `modspec`
- 7: model label: `modlab`
- 8: whether all metabolites vs all metabolites is run: `allvsall`
- 9: weight variables: `wgtcov`
- 10: offset variables: `offcov`

Examples

```
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
modeldata <- getModelData(exmetabdata, modlabel="1 Gender adjusted")
```

glm.options

options list for glm

Description

A list of 6:

- **family** One of: "binomial", "gaussian", "Gamma", "inverse.gaussian", "poisson", "quasi", "quasibinomial", "quasipoisson". The default is "gaussian".
- **link** NULL or a string for the link function to use (see [family](#)). The default is to use the canonical link for family.
- **weights** A variable name to specify weights. The default is NULL.
- **offset** A variable name to specify an offset. The default is NULL.
- **control** See [glm](#). The default is [glm.control](#).
- **singular.ok** See [glm](#). The default is TRUE.

Examples

```
model.options <- list(family="binomial", weights="weightVarInData")
```

lm.options	<i>options list for lm</i>
------------	----------------------------

Description

A list of 4:

- `weights` A variable name to specify weights. The default is NULL.
- `offset` A variable name to specify an offset. The default is NULL.
- `tol` See [lm](#). The default is 1e-7.
- `singular.ok` See [lm](#). The default is TRUE.

Examples

```
model.options <- list(weights="weightVarInData")
```

MetaOutputColumns	<i>Meta Analysis Output Columns</i>
-------------------	-------------------------------------

Description

Depending on the model run and options specified, all the below names may not appear in the data frame returned from [runMeta](#).

- `outcome_uid` The harmonized outcome variable
- `exposure_uid` The harmonized exposure variable
- `term` For a continuous exposure, this will be the same as `exposure_uid`. For a categorical exposure, it will be the dummy variable for the exposure.
- `n.cohort` The number of included cohorts for the estimates.
- `n.sub` Total number of subjects.
- `fixed.pvalue` P-value for the fixed-effects model.
- `random.pvalue` P-value for the random-effects model.
- `fixed.estimate` Estimate for the fixed-effects model.
- `fixed.std.error` Estimated standard error of `fixed.estimate`. This will not appear for correlation models.
- `random.estimate` Estimate for the random-effects model.
- `random.std.error` Estimated standard error of `random.estimate`. This will not appear for correlation models.
- `fixed.estimate.L` Lower 95% confidence limit for `fixed.estimate`.
- `fixed.estimate.U` Upper 95% confidence limit for `fixed.estimate`.
- `random.estimate.L` Lower 95% confidence limit for `random.estimate`.
- `random.estimate.U` Upper 95% confidence limit for `random.estimate`.
- `het.pvalue` P-value for Cochran's Q test of heterogeneity across the cohorts.
- `stratavar` Stratum variable(s)

- strata Stratum level(s)
- strata.fixed.het.pvalue P-value for Cochran's Q test of heterogeneity across the strata using the fixed-effects meta-analysis estimates.
- strata.fixed.het.df Degrees of freedom for the above test.
- strata.random.het.pvalue P-value for Cochran's Q test of heterogeneity across the strata using the random-effects meta-analysis estimates.
- strata.random.het.df Degrees of freedom for the above test.

Details

Correlation models will not contain columns for fixed.std.error and random.std.error. Instead, there will be columns for lower and upper confidence limits of fixed.estimate and random.estimate.

meta_calc	<i>Main function that performs the meta-analysis calculations.</i>
-----------	--

Description

Main function that performs the meta-analysis calculations.

Usage

```
meta_calc(beta, se)
```

Arguments

beta	matrix or vector of betas. If a matrix, then the rows represent the metabolites and the columns represent the cohorts.
se	matrix or vector of the standard errors for beta. This object must be in the same order and have the same dimension as beta.

Value

List containing the results from fixed-effect and random-effect meta-analyses along with Cochran's Q test for heterogeneity.

meta_opfile	<i>Options file for meta-analyses</i>
-------------	---------------------------------------

Description

An Excel file containing models and options for the runAllMeta function

Details

The file should contain sheets **META_MODELS** and **META_TYPES**. Each sheet is optional. The **META_MODELS** sheet should have a column called MODEL containing the models for meta-analysis. This list of models can be a subset of models defined by the input files. This sheet can also have an optional column called MODEL_TYPE that links to the **META_TYPES** sheet defining the options for each model. See the example file in /inst/extdata/cometsMetaInput.xlsx.

meta_options	<i>Meta-analysis options</i>
--------------	------------------------------

Description

A list of options for the runMeta function

Details

- `min.n.cohort` Minimum number of cohorts to include when meta-analyzing each metabolite. The default is 2.
- `min.nsub.cohort` Minimum number of subjects in a cohort for a metabolite to be included from that cohort. The default is 25.
- `min.nsub.total` Minimum number of subjects in all cohorts for a metabolite to be meta-analyzed. The default is 50.
- `cohorts.include` Character vector of cohorts to include. The default is NULL.
- `cohorts.exclude` Character vector of cohorts to exclude. The default is NULL.
- `output.type` Type of output file, either "xlsx" for an Excel worksheet or "rda" for an R object file created with the `save()` function. The default is "xlsx".
- `strata.exclude.het.test` A list of stratification levels to be excluded from the test for heterogeneity. This list has the form `list(var1=vec1, var2=vec2, ...)`, where `var1`, `var2`, ... are stratification variables, and `vec1`, `vec2`, ... are vectors of stratification levels to be removed from the test. The default is NULL.

ModelSummary	<i>ModelSummary table</i>
--------------	---------------------------

Description

The ModelSummary data frame contains one row of model summary results for each exposure/outcome combination. Depending on the model run and options specified, all the below names may not appear in the data frame.

- `adjspec` Original adjustment variables specified
- `adjvars` Adjustment variables included in the model
- `adjvars.removed` Adjustment variables removed from the model
- `adj_uid` Adjustment variable universal ids
- `adj.r.squared` Adjusted R-squared
- `aic` Akaike information criterion
- `bic` Bayesian information criterion
- `cohort` String passed into [runModel](#)
- `converged` TRUE or FALSE for model convergence
- `deviance` Deviance of the fitted model
- `df.null` NULL model degrees of freedom

- `df.residual` Residual degrees of freedom
- `exposure` Exposure variable
- `exposure_uid` Exposure universal id
- `exposurespec` Exposure variable
- `loglik` Log-likelihood of the fitted model
- `message` Error message produced from the modeling function
- `model` Model label from [getModelData](#)
- `model_function` Model function used in [runModel](#)
- `model_number` Model number used in [runAllModels](#)
- `nobs` Number of observations used
- `null.deviance` Deviance of the NULL model
- `outcome` Outcome variable
- `outcomespec` Outcome variable
- `outcome_uid` Outcome universal id
- `run` Run number that can be used to link with the [Effects](#) table
- `runmode` "Batch" or "Interactive"
- `r.squared` R-squared, the fraction of variance explained by the model
- `sigma` Square root of the estimated variance of the random error
- `strata` Stratum level(s)
- `strata` Stratum variable(s)
- `term` Variable in the model
- `wald.pvalue` P-value from the Wald test of the exposure variable. Note that this test may be a multi-df test if the exposure is categorical.

Details

Missing values will appear if a model did not converge, produced an error, or not run because of too many missing values in the outcome.

options	<i>options list</i>
---------	---------------------

Description

A list of 19:

- `check.cor.cutoff` Cutoff value to remove highly correlated columns in the design matrix. The default value is 0.97.
- `check.cor.method` Correlation method to remove highly correlated columns in the design matrix. It must be one of "spearman", "pearson", "kendall". The default value is "spearman".
- `check.design` TRUE or FALSE to check the design matrix for linearly dependent columns, highly correlated columns, or for being ill-conditioned whenever it is updated. The default is TRUE.

- `check.illCond` TRUE or FALSE to check for an ill-conditioned design matrix. The default is TRUE.
- `check.nsubjects` Minimum number of subjects. The default is 25.
- `max.npairwise` The maximum number of metabolites to process the "all pairwise correlations" model. The default is 100.
- `max.nstrata` The maximum number of strata for a stratified analysis. The default is 10.
- `model` String for the model function. Currently, it must be one of "correlation", "lm", "glm", "coxph", or "clogit". The default is "correlation".
- `model.options` List of options specific for the model. See [correlation.options](#), [glm.options](#), [lm.options](#), [coxph.options](#) and [clogit.options](#) for options specific to `model="correlation"`, `"lm"`, `"glm"`, `"coxph"`, `"clogit"` respectively. The default is NULL.
- `output.ci_alpha` Confidence interval level for estimated from glm models. This option must be a number ≥ 0 and < 1 , where 0 is for not creating confidence intervals. The default value is 0.95.
- `output.Effects` A string to define the terms output in the returned [Effects](#) and [ModelSummary](#) data frames. Currently, it must be "exposure" or "all". If set to "all", then summary statistics for the exposure and adjustment variables will be output. Otherwise, only summary statistics for the exposure will be output. This option is ignored with `model = "correlation"`. The default is "exposure".
- `output.exp_parms` TRUE, FALSE or NULL to exponentiate parameter estimates. Standard errors are obtained from the delta method. The default is NULL, so that estimates from logistic regression and survival models will be exponentiated, and not otherwise.
- `output.metab.cols` Character vector of column names in the METABOLITES sheet to be output in the [ModelSummary](#) and [Effects](#) data frames. Metabolite ids are matched first using the `outcomespec` column and then using the `exposurespec` column. The default is "metabolite_name".
- `output.ModelSummary` A string to defines the columns output in the returned [ModelSummary](#) data frame. Currently, it must be "anova" or "all". This option is ignored with `model = "correlation"`. The default is "anova".
- `output.type` "rda" or "xlsx" to define the type of output file(s) when [runAllModels](#) is called. See `output.common.cols` and `output.merge`. The default is "xlsx".
- `output.merge` One of the following strings: "all", "by_function", "by_model_type" or "none". This option is used to merge model results together in order to reduce the number of output files. Setting to "all" will merge all model results together and output them to a single file. Setting to "by_function" will merge results from the same model function together and output to a file with the model function contained in the output file name. Similarly for "by_model_type", where the `MODEL_TYPE` column in the `MODELS` sheet of the input Excel file is used to identify the models that will be merged together. Setting to "none" will not merge results. The default is "none".
- `chemEnrich` 0 or 1 to run a chemical class enrichment (0=no, 1=yes) using RaMP. The default is 0.
- `chemEnrich.adjPvalue` The BH-adjusted p-value cutoff to select metabolites for chemical class enrichment. The default is 0.05.

Details

Before any analysis is performed, an initial design matrix is constructed using the above options as follows:

1. Adjustment variables with less than two distinct non-missing values, or with less than `check.nsubjects` non-missing values are removed.
2. The design matrix is created from the remaining adjustment variables and any linearly dependent columns are removed.
3. If `check.cor.cutoff > 0`, then highly correlated columns are removed by computing the correlation matrix `cor_matrix = cor(design_matrix, method=check.cor.method)`.
4. If `check.illCond` is TRUE, then the function `subselect::trim.matrix` is applied to the correlation matrix to determine if additional columns will be removed.

If `check.design` is TRUE, then steps 2-4 are repeated each time an exposure variable is added to the design matrix or when rows of the design matrix are removed due to missing values in an outcome variable.

Examples

```
# Logistic regression with all default options
model.op <- list(family="binomial")
op <- list(model="glm", model.options=model.op)
# Compute Pearson correlations requiring at least 100 subjects
model.op <- list(method="pearson")
op <- list(model="correlation", check.nsubjects=100, model.options=model.op)
```

OutputCSVResults

Create output CSV file

Description

Create output CSV file

Usage

```
OutputCSVResults(filename, dataf, cohort = "")
```

Arguments

<code>filename</code>	name of CSV file and can include path
<code>dataf</code>	correlation output (from function <code>runCorr()</code>)
<code>cohort</code>	cohort name

Value

the filename of the CSV file with results named with cohort

Examples

```
## Not run:
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
modeldata <- getModelData(exmetabdata, exposures="age", modlabel="1 Gender adjusted",
  outcomes=c("lactose", "lactate"))
corrmatrix <- runCorr(modeldata, exmetabdata, "DPP")
```

```
# Get correlation results
OutputCSVResults(filename="corr",dataf=corrmatrix,cohort="DPP")
# Get harmonization results
OutputCSVResults(filename="harmonization",dataf=exmetabdata$metab,cohort="DPP")

## End(Not run)
```

OutputListToExcel	<i>Create an excel xlsx file from a list of data frames</i>
-------------------	---

Description

Create an excel xlsx file from a list of data frames

Usage

```
OutputListToExcel(filename, obj)
```

Arguments

filename	Name of file and can include path. It must have a ".xlsx" extension.
obj	List of data frames or matrices

OutputXLSResults	<i>Create output XLSX file</i>
------------------	--------------------------------

Description

Create output XLSX file

Usage

```
OutputXLSResults(filename, data1, cohort = "")
```

Arguments

filename	name of file and can include path
data1	data list to output (each item on list outputs to a worksheet)
cohort	cohort name

Value

the filename of the XLSX file with results named with cohort

Examples

```

dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
modeldata <- getModelData(exmetabdata,exposures="age",modlabel="1 Gender adjusted",
outcomes=c("lactose","lactate"))
# Get descriptive data
descdata <-runDescrip(exmetabdata)
OutputXLSResults(filename="corr",data1=descdata,cohort="DPP")

```

plotMinvalues	<i>Plot the distribution of the number of missing values for each metabolite</i>
---------------	--

Description

Plot the distribution of the number of missing values for each metabolite

Usage

```

plotMinvalues(
  cometsdata,
  title = "Distribution of the Number/Missing Values",
  xlabel = "Number of minimum/missing values",
  ylabel = "Frequency",
  xylabelsize = 12,
  titlesize = 16
)

```

Arguments

cometsdata	output of readCOMETSinput function
title	main title for the plot (default is "Distribution of the Number/Missing Values")
xlabel	x-axis label (default is "Number of minimum/missing values")
ylabel	y-axis label (default is "Frequency")
xylabelsize	size of x and y labels (default=8)
titlesize	size of title (default, 20)

Value

a distribution plot

Examples

```

dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
plotMinvalues(exmetabdata)

```

plotVar	<i>Plot the variance distribution of transformed metabolite abundances</i>
---------	--

Description

Plot the variance distribution of transformed metabolite abundances

Usage

```
plotVar(
  cometsdata,
  title = "Distribution of Variance",
  titlesize = 16,
  xlabel = "Variance of transformed metabolite abundances",
  ylabel = "Frequency",
  xylabelsize = 12
)
```

Arguments

cometsdata	output of readCOMETSinput function
title	main title for the plot (default is "Distribution of Variance")
titlesize	size of title (default, 20)
xlabel	x-axis label (default is "Variance of transformed metabolite abundances")
ylabel	y-axis label (default is "Frequency")
xylabelsize	size of x and y labels (default=8)

Value

a distribution plot

Examples

```
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
plotVar(exmetabdata)
```

readCOMETSinput	<i>Read in Excel file that contains metabolite data, covariate data, models, and model options.</i>
-----------------	---

Description

Read in Excel file that contains metabolite data, covariate data, models, and model options.

Usage

```
readCOMETSinput(file)
```

Arguments

file path of Excel file to be read in. This file must contain sheets with names **Metabolites**, **SubjectMetabolites**, **SubjectData**, **VarMap**, and optionally **Models**, **Model_Types** (see details).

Details

Additional information regarding each sheet in the input Excel file is given below.

Metabolites

A table with the columns METABID, METABOLITE_NAME, and possibly other columns of information about the metabolites. The METABID column is used for harmonizing the metabolite names across different cohorts when meta-analyses are performed.

SubjectMetabolites

A table with the subject ids in the first column and metabolites as the other columns.

SubjectData

A table with the subject ids in the first column and covariates as the other columns.

VarMap

A table with at least the required columns VARREFERENCE, COHORTVARIABLE, VARTYPE, VARDEFINITION, and ACCEPTED_VALUES. The COHORTVARIABLE column must contain names that match the column names in the **SubjectData** table. These names will be renamed to their corresponding name in the VARREFERENCE column. The VARTYPE column should have values continuous or categorical for each row. The ACCEPTED_VALUES column defines the allowed values that the variable should have, and an error will be thrown if the variable is outside of the accepted values. For a categorical variable, ACCEPTED_VALUES should be a comma separated list of values such as '1, 2, 3'. For a continuous variable, ACCEPTED_VALUES should be a range of the form: (a, b), (a, b], [a, b), or [a, b], where parentheses denote exclusion of the value, and brackets denote inclusion of the value.

Models

A table where each row represents a model to be run, and with columns MODEL, OUTCOMES, EXPOSURE, ADJUSTMENT, STRATIFICATION, WHERE, and optionally MODEL_TYPE, TIME, GROUP. All variable names in this table must match variable names in the VARREFERENCE column of the **VarMap** sheet. The MODEL column is a label for the model. The OUTCOMES and EXPOSURE columns define the outcome and exposure variables for the model. Use All metabolites to specify that all metabolite variables are to be included as outcomes or exposures, otherwise use a space separated list of variable names. The ADJUSTMENT column contains a space separated list of covariate adjustment variables; use an empty cell for no covariate adjustment. The STRATIFICATION column is used for stratified analyses, with a space separated list of stratification variables. If more than one stratification variable is specified, then the strata are defined by all unique combinations of the stratification variables that appear in the data. The WHERE column is used to define a subset of subjects to include in the analysis, and has the form variable operator value, where operator can be one of the following >, <, >=, <= !=, =. An example WHERE condition is age > 50, which will include all subjects older than 50 in the analysis. Multiple WHERE conditions must be separated by a comma and are logically connected with the & operator. For example, the WHERE condition age > 50 , bmi >= 22 will include the subjects older than 50 AND with bmi >= 22. Values in the MODEL_TYPE column must match with the MODEL_TYPE column in the **Model_Types** sheet. The TIME column is only required when survival models are run. This column can contain a single time variable or two time variables separated by a space. The GROUP column is only required when conditional logistic regression models are run. This column can contain only a single variable that defines the groups (sets, strata). This sheet is not required when running in interactive mode, but is required when running in batch mode.

Model_Types

A table where each row specifies an option and has columns MODEL_TYPE, FUNCTION, OPTION, and VALUE. For an example sheet and additional information about this sheet, see the Excel file /extdata/cometsInput.xlsx. This sheet is optional, but is required when the **Models** sheet contains the column MODEL_TYPE.

Value

a list comprising of data and information needed for [getModelData](#).

Examples

```
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
```

runAllMeta	<i>This function allows users to run meta-analyses on all models or a subset of models</i>
------------	--

Description

This function allows users to run meta-analyses on all models or a subset of models

Usage

```
runAllMeta(filesFolders, out.dir, opfile = NULL)
```

Arguments

- filesFolders Character vector of files and/or folders that contain the output files from [runAllModels](#). Valid file extensions are ".xlsx", ".rda", ".zip", ".tar", and ".tar.gz". Zip and tar files must contain files with extensions ".xlsx" or ".rda".
- out.dir Output directory to save the results for each model.
- opfile Excel file containing the models and options. See [meta_opfile](#). The default is NULL.

runAllModels	<i>This function allows users to run all models that are provided in the "Models" sheet of the input Excel file.</i>
--------------	--

Description

This function allows users to run all models that are provided in the "Models" sheet of the input Excel file.

Usage

```
runAllModels(readData, cohortLabel = "", writeToFile = T)
```

Arguments

readData	list from readCOMETSinput
cohortLabel	cohort label (e.g. DPP, NCI, Shanghai)
writeToFile	T/F (whether or not to write results for each model into separate xlsx files). Files are written to current directory. Default is TRUE.

Value

A list of return objects from [runModel](#) or [runCorr](#). The *i*th element in this list is the output from the *i*th model run.

Examples

```
## Not run:
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
allmodeloutput <- runAllModels(exmetabdata)

## End(Not run)
```

runCorr	<i>Calculate correlations for input model.</i>
---------	--

Description

Calculate correlations for input model.

Usage

```
runCorr(modeldata, metabdata, cohort = "")
```

Arguments

modeldata	list from function getModelData
metabdata	metabolite data list from readCOMETSinput
cohort	cohort label (e.g DPP, NCI, Shanghai)

Details

This function is a special case of [runModel](#) with the option `op$model = "correlation"`, however for backwards compatibility, it returns a data frame as in the original version of the **COMETS R** package.

Value

data frame with each row representing the correlation for each combination of outcomes and exposures represented as specified in the model (*spec), label (*lab), and universal id (*_uid) with additional columns for n, pvalue, method of model specification (Interactive or Batch), universal id for outcomes (outcome_uid) and exposures (exposure_uid) name of the cohort, adjustment (adjvars) and stratification (stratavar,strata) variables. Attribute of dataframe includes ptime for processing time of model run.

Examples

```
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
modeldata <- getModelData(exmetabdata,exposures="age",modlabel="1 Gender adjusted",
outcomes=c("lactose","lactate"), modelspec="Interactive")
corrmatrix <- runCorr(modeldata,exmetabdata, "DPP")
```

runDescrip

This function provides a description of the input data (for categorical data, the number of samples of each type; for continous data, the median and other statistics for each variable)

Description

This function provides a description of the input data (for categorical data, the number of samples of each type; for continous data, the median and other statistics for each variable)

Usage

```
runDescrip(readData)
```

Arguments

readData list from readComets

Value

a list with 2 data frames, continuous and categorical summaries. Type of variable is defined in varmap

Examples

```
## Not run:
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
allmodeloutput <- runAllModels(exmetabdata)
# Get descriptive data
descdata <-runDescrip(exmetabdata)
OutputXLSResults(filename="corr",data1=descdata,cohort="DPP")

## End(Not run)
```

runMeta	<i>This function allows users to run a single meta-analysis</i>
---------	---

Description

This function allows users to run a single meta-analysis

Usage

```
runMeta(filevec, op = NULL)
```

Arguments

filevec	Character vector of files that contain the output files from runModel or runAllModels . Valid file extensions are ".xlsx", and ".rda".
op	A list containing the options to use. See meta_options . The default is NULL.

Value

List of data frames containing the results and information

runModel	<i>Main function for running the models</i>
----------	---

Description

Main function for running the models

Usage

```
runModel(modeldata, metabdata, cohortLabel = "", op = NULL, out.file = NULL)
```

Arguments

modeldata	list from function getModelData
metabdata	metabolite data list from readCOMETInput
cohortLabel	cohort label (e.g DPP, NCI, Shanghai)
op	list of options when running in Interactive mode (see options).
out.file	NULL or the name of an output file to save the results. The file extension must be ".xlsx" or ".rda".

Details

This function will check for stratification variables, and if present run within each stratum. The design matrix is checked for validity (see [options](#)). When running in Batch mode, the options are obtained from the Options sheet in the excel file.

Value

A list of objects with names `ModelSummary`, `Effects`, `Errors_Warnings`, `Table1`, `Info`.

Important: check the `adjvars.removed` column in the `ModelSummary` data frame to see if any adjustment variables were dropped from the model, and use caution interpreting results when variables are removed. The `Errors_Warnings` object may also contain additional variables removed. Attribute of this list includes `ptime` for processing time of model run.

Examples

```
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
modeldata <- getModelData(exmetabdata,exposures="age",modlabel="1 Gender adjusted",
  outcomes=c("lactose","lactate"))
obj <- runModel(modeldata,exmetabdata, cohortLabel="DPP")
```

showCorr

Function that returns top N lines of the `runCorr` output

Description

Function that returns top N lines of the `runCorr` output

Usage

```
showCorr(corr, nlines = 50)
```

Arguments

<code>corr</code>	returned object from <code>runCorr</code>
<code>nlines</code>	number of lines to return (default 50)

Value

first 50 lines of output

Examples

```
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
modeldata <- getModelData(exmetabdata,modlabel="1 Gender adjusted")
corrmatrix <- runCorr(modeldata,exmetabdata,"DPP")
showCorr(corrmatrix)
```

showHClust	<i>Show interactive heatmap using heatmaply_cor with hierarchical clustering</i>
------------	--

Description

This function outputs a heatmap with hierarchical clustering. It thus requires you to have at least 2 outcome and 2 exposure variables in your models.

Usage

```
showHClust(
  ccorrList,
  strata = NULL,
  clust = TRUE,
  colscale = "RdYlBu",
  showticklabels = TRUE
)
```

Arguments

ccorrList	correlation object (output of runCorr)
strata	Only valid if ccorrList is from a stratified analysis. If NULL, then results from the first stratum will be used in the plot.
clust	TRUE or FALSE to show hierarchical clustering. The default is TRUE.
colscale	colscale, can be custom or named ("Hots", "Greens", "Blues", "Greys", "Purples") see RColorBrewer_colors
showticklabels	TRUE or FALSE to show axis labels. The default is TRUE.

Value

a heatmap with outcomes as rows and exposures in columns.

References

For colorscale reference: [RColorBrewer_colors](#)

Examples

```
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
modeldata <- getModelData(exmetabdata, modelspec="Interactive",
  exposures=c("age", "bmi_grp"))
corrmatrix <- runCorr(modeldata, exmetabdata, "DPP")
showHClust(corrmatrix)
```

showHeatmap

*Show interactive heatmap using plot_ly***Description**

Show interactive heatmap using plot_ly

Usage

```
showHeatmap(
  ccorrList,
  strata = NULL,
  rowsortby = "estimate",
  plotght = 700,
  plotwid = 800,
  colscale = "RdYlBu"
)
```

Arguments

ccorrList	correlation object (output of runCorr)
strata	Only valid if ccorrList is from a stratified analysis. If NULL, then results from the first stratum will be used in the plot.
rowsortby	How row labels are sorted
plotght	Plot height default 700
plotwid	Plot width default 800
colscale	colscale, can be custom or named ("Hots","Greens","Blues","Greys","Purples") see https://plot.ly/ipython-notebooks/color-scales/

Value

a heatmap with outcomes as rows and exposures in columns.

References

For colorscale reference: <https://plot.ly/ipython-notebooks/color-scales/>

Examples

```
## Not run:
dir <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
modeldata <- getModelData(exmetabdata,modlabel="1 Gender adjusted")
corrmatrix <-runCorr(modeldata,exmetabdata,"DPP")
showHeatmap(corrmatrix)

## End(Not run)
```

showModel	Function that displays the first N rows of each data frame in the the runModel output.
-----------	--

Description

Function that displays the first N rows of each data frame in the the [runModel](#) output.

Usage

```
showModel(obj, nlines = 10)
```

Arguments

obj	returned object from runModel
nlines	number of lines to display (default 10)

Examples

```
dir      <- system.file("extdata", package="RcometsAnalytics", mustWork=TRUE)
csvfile  <- file.path(dir, "cometsInputAge.xlsx")
exmetabdata <- readCOMETSinput(csvfile)
modeldata <- getModelData(exmetabdata, modlabel="1 Gender adjusted")
result    <- runModel(modeldata, exmetabdata, cohortLabel="DPP")
showModel(result)
```

Table1	Non-metabolite Variable Summary Table
--------	---------------------------------------

Description

Columns in Table1. Depending on the model run and options specified, all the below names may not appear in the data frame.

- category Category for categorical variables only
- in.model How variable enters the model (outcome, exposure, adjustment, time, group, weight, offset)
- max Maximum value
- mean Mean value
- median Median value
- min Minimum value
- n Number of non-missing observations
- n.missing Number of missing observations
- n.outcomeEqual0 Number of non-missing observations with outcome = 0
- n.outcomeEqual1 Number of non-missing observations with outcome = 1
- n.unique Number of unique non-missing observations

- quartile1 25th percentile
- quartile3 75th percentile
- stratavar Stratum variable(s)
- strata Stratum level(s)
- type Either continuous or categorical
- variable Variable name in the model

Details

The columns max, mean, median, min, n.missing, n.unique, quartile1, and quartile3 are for continuous variables only.
